

# Introduction to AMBA APB

2013 – 2017 - 2018

Ando Ki, Ph.D.  
(adki@future-ds.com)

## Evolution of AMBA Standards

- CHI - Coherent Hub Interface - The highest performance, used in networks and servers
- ACE - AXI Coherency Extensions - Used in big.LITTLE™ systems for smartphones, tablets, etc.
- AXI - Advanced eXtensible Interface - The most widespread AMBA interface. Connectivity up to 100's of Masters and Slaves in complex SoC's
- AHB - Advanced High-Performance Bus - The main system bus in microcontroller usage
- APB - Advanced Peripheral Bus - Minimal gate count for peripherals
- ATB - Advanced Trace Bus - For moving trace data around the chip

# AMBA APB bus

AHB: Advanced High-performance bus  
ASB: Advanced System Bus  
APB: Advanced Peripheral Bus  
FRC: Free-running counter

AHB Example AMBA SYstem Technical Reference Manual, DDI0170A, ARM, 1999

# APB

- Low-power extension to the system bus (AHB/ASB)
  - ◆ Minimal power consumption
  - ◆ Reduced interface complexity.
- Local secondary bus that is encapsulated as a single AXI/AHB slave device
- Features
  - ◆ Low bandwidth
  - ◆ Unpipelined bus interface.
    - ✦ address and control valid throughout the access → **unpipelined**
  - ◆ All signal transitions are only related to the rising edge of the clock → **synchronous**

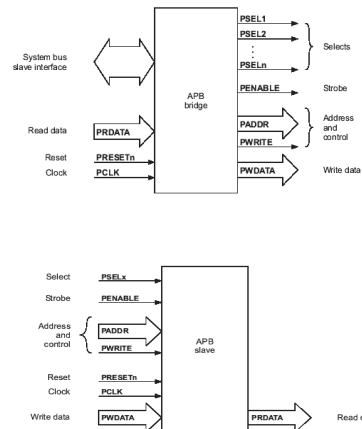

## AMBA APB bus versions

AMBA 4 APB	AMBA 3 APB	AMBA 2 APB
<ul style="list-style-type: none"><li>■ an extension of AMBA 3 APB</li><li>■ transaction protection (normal/privileged, secure/non-secure, data/instruction)</li><li>■ Sparse data transfer (partial access)</li></ul>	<ul style="list-style-type: none"><li>■ an extension of AMBA 2 APB</li><li>■ wait state supported</li><li>■ error response supported</li></ul>	<ul style="list-style-type: none"><li>■ low power</li><li>■ latched address and control</li><li>■ simple interface</li><li>■ suitable for many peripherals</li></ul>

## AMBA 2.0 APB signals

Name	Description
<b>PCLK</b> Bus clock	The rising edge of <b>PCLK</b> is used to time all transfers on the APB.
<b>PRESETn</b> APB reset	The APB bus reset signal is active LOW and this signal will normally be connected directly to the system bus reset signal.
<b>PADDR[31:0]</b> APB address bus	This is the APB address bus, which may be up to 32-bits wide and is driven by the peripheral bus bridge unit.
<b>PSELx</b> APB select	A signal from the secondary decoder, within the peripheral bus bridge unit, to each peripheral bus slave x. This signal indicates that the slave device is selected and a data transfer is required. There is a <b>PSELx</b> signal for each bus slave.
<b>PENABLE</b> APB strobe	This strobe signal is used to time all accesses on the peripheral bus. The enable signal is used to indicate the second cycle of an APB transfer. The rising edge of <b>PENABLE</b> occurs in the middle of the APB transfer.
<b>PWRITE</b> APB transfer direction	When HIGH this signal indicates an APB write access and when LOW a read access.
<b>PRDATA</b> APB read data bus	The read data bus is driven by the selected slave during read cycles (when <b>PWRITE</b> is LOW). The read data bus can be up to 32-bits wide.
<b>PWDATA</b> APB write data bus	The write data bus is driven by the peripheral bus bridge unit during write cycles (when <b>PWRITE</b> is HIGH). The write data bus can be up to 32-bits wide.

Introduction to AMBA APB ( 7 )

## AMBA 2.0 APB timing

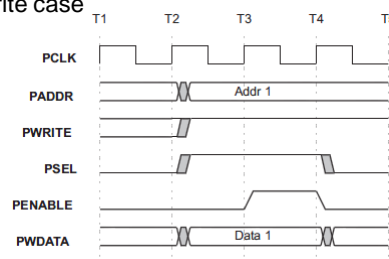

### Read case

### It is simple.

- There is no way to delay or wait.
- There is no way to specify part of data.
- There is no way to notify any status from slave, i.e., all transaction should be completed successfully.

### Write case

Introduction to AMBA APB ( 8 )

# AMBA 3.0 APB 1.0 signals

Signal	Source	Description
PCLK	Clock source	Clock. The rising edge of PCLK times all transfers on the APB.
PRESETn	System bus equivalent	Reset. The APB reset signal is active LOW. This signal is normally connected directly to the system bus reset signal.
PADDR	APB bridge	Address. This is the APB address bus. It can be up to 32 bits wide and is driven by the peripheral bus bridge unit.
PSELx	APB bridge	Select. The APB bridge unit generates this signal to each peripheral bus slave. It indicates that the slave device is selected and that a data transfer is required. There is a PSELx signal for each slave.
PENABLE	APB bridge	Enable. This signal indicates the second and subsequent cycles of an APB transfer.
PWRITE	APB bridge	Direction. This signal indicates an APB write access when HIGH and an APB read access when LOW.
PWDATA	APB bridge	Write data. This bus is driven by the peripheral bus bridge unit during write cycles when PWRITE is HIGH. This bus can be up to 32 bits wide.
PREADY	Slave interface	Ready. The slave uses this signal to extend an APB transfer.
PRDATA	Slave interface	Read Data. The selected slave drives this bus during read cycles when PWRITE is LOW. This bus can be up to 32-bits wide.
PSLVERR	Slave interface	This signal indicates a transfer failure. APB peripherals are not required to support the PSLVERR pin. This is true for both existing and new APB peripheral designs. Where a peripheral does not include this pin then the appropriate input to the APB bridge is tied LOW.

- A ready signal, PREADY, to extend an APB transfer.
- An error signal, PSLVERR, to indicate the failure of a transfer.

Read with error

# AMBA 4.0 APB 2.0 signals

Signal	Source	Description
PCLK	Clock source	Clock. The rising edge of PCLK times all transfers on the APB.
PRESETn	System bus equivalent	Reset. The APB reset signal is active LOW. This signal is normally connected directly to the system bus reset signal.
PADDR	APB bridge	Address. This is the APB address bus. It can be up to 32 bits wide and is driven by the peripheral bus bridge unit.
PPROT	APB bridge	Protection type. This signal indicates the normal, privileged, or secure protection level of the transaction and whether the transaction is a data access or an instruction access.
PSELx	APB bridge	Select. The APB bridge unit generates this signal to each peripheral bus slave. It indicates that the slave device is selected and that a data transfer is required. There is a PSELx signal for each slave.
PENABLE	APB bridge	Enable. This signal indicates the second and subsequent cycles of an APB transfer.
PWRITE	APB bridge	Direction. This signal indicates an APB write access when HIGH and an APB read access when LOW.
PWDATA	APB bridge	Write data. This bus is driven by the peripheral bus bridge unit during write cycles when PWRITE is HIGH. This bus can be up to 32 bits wide.
PSTRB	APB bridge	Write strobes. This signal indicates which byte lanes to update during a write transfer. There is one write strobe for each eight bits of the write data bus. Therefore, PSTRB[n] corresponds to PWDATA[(8n + 7):(8n)]. Write strobes must not be active during a read transfer.
PREADY	Slave interface	Ready. The slave uses this signal to extend an APB transfer.
PRDATA	Slave interface	Read Data. The selected slave drives this bus during read cycles when PWRITE is LOW. This bus can be up to 32-bits wide.
PSLVERR	Slave interface	This signal indicates a transfer failure. APB peripherals are not required to support the PSLVERR pin. This is true for both existing and new APB peripheral designs. Where a peripheral does not include this pin then the appropriate input to the APB bridge is tied LOW.

- Protection signals, PPROT[2:0], to provide protection against illegal transactions
- Strobe signals, PSTRB[x:0], enable sparse data transfer on the write data bus. Each write strobe signal corresponds to one byte of the write data bus. When asserted HIGH, a write strobe indicates that the corresponding byte lane of the write data bus contains valid information.

## AMBA 4.0 APB 2.0 protection and write strobe

### Protection type signals

PPROT[2:0]	Protection level
[0]	1 = privileged access 0 = normal access
[1]	1 = nonsecure access 0 = secure access
[2]	1 = instruction access 0 = data access

There is one write strobe for each eight bits of the write data bus, so **PSTRB[n]** corresponds to **PWDATA[(8n + 7):(8n)]**. Figure below shows this relationship on a 32-bit data bus.
